

The AI Operations Framework

Give your company somewhere to live — and an executive layer that can actually work in it.

A STEP-BY-STEP START

MeshPro × Expectus

Where does your company actually live?

Ask two people in the same company the same question and you get two answers. Both of them are honest.

In people's heads

The person who knows how it works is on holiday, and the work stops until Tuesday.

In a thread somewhere

It was decided. Nobody can find where, so it gets decided again, differently.

In one spreadsheet

It is accurate. One person can open it, and they are the bottleneck for everything.

None of this is a discipline problem. There is simply nowhere for the answer to live, so it lives in whoever last dealt with it.

One page that cannot tell you something untrue

Not a dashboard somebody keeps up to date. A page rebuilt from your own notes every time, by a machine that fails rather than guesses.

1

It is generated

Nobody maintains it. It is rebuilt from the notes, so it cannot quietly go stale while everyone still trusts it.

2

It is checked

Thirteen checks run over it. If the page would say nine and there are seven, the build fails.

3

It says what is waiting

Named, not counted — and what happens if nothing is done about each one.

Four rules. Everything else follows.

1

A fact has one home

If the same fact is true in two places, one of them is lying and you cannot tell which.

2

Every surface is generated

The page, the register, the agents. You never edit those — you edit the note that owns the fact.

3

A check fails on a false claim

Not a warning nobody reads. The build stops.

4

Only a person decides

Publishing, sending, spending, deleting. The machine prepares it all and stops.

A folder of text files. That is the whole trick.

No database, no platform, no account to create. It sits on your own computer and you can read every file of it in Notepad.

THE VAULT

A folder

Plain text notes, one fact each. Yours, on your machine. It still works if we never speak again.

TO READ AND WRITE IT

Obsidian

Free, optional, and much nicer than Notepad. It is a reader for the folder — nothing lives inside it.

TO DO THE WORK

Claude

Connect the folder to a project. It reads the notes, writes the notes, and runs the checks.

You do not install Python, git, or anything else. You make a folder and you write sentences.

Twenty minutes, four steps

None of these is a command. All four are things you say or click.

1 **Make a folder**

Anywhere. Name it after your company. Empty is correct.

2 **Make a project in Claude, and connect the folder**

A project remembers. Next week starts where today ended instead of starting from nothing.

3 **Ask for the setup, in one sentence**

It pulls the framework, installs it and runs the check. About a minute.

4 **Open the page it made**

Thirteen folders, three working agents, eight workflows, one page — and an honest report of what is missing.

This is the whole of the technical part:

**Set up the AI Operations Framework in my connected folder.
Pull it from the repository and run the install, then tell me
what it made.**

Or your own words. It is read for intent, not matched against a format — if a session ever answers you with syntax to type, that session is wrong.

Name your departments before anything else

Not because it is tidy. Because everything else needs an owner, and a department is where owners come from.

Three to six. Not twelve.

Say them out loud, in your own words — sales, delivery, the money stuff, the client stuff. If two of them would never disagree about anything, they are one department.

The same person can be behind several. The department is the unit of accountability, not of headcount.

Write down what each one does not own

The argument about where something belongs is cheaper now than in six months. Each department names the work people will assume is its and is not.

One department, one executive. With two, each assumes the other answered.

An executive layer that can do work

Each department note compiles into an agent that answers for that department and nothing else. Adding one later is the same sentence again.

One executive per department · one architect across all of them

Write down the process that annoys you most

Not the most important one. The one that goes wrong most often — because that is the one people will check you on.

It asks you the awkward questions

What starts it, what "done" actually means, who owns it, and — the part nobody writes down — where it breaks and how often.

It records the mess honestly, because a workflow note that describes the tidy version is worse than none.

Two marks, because they fail separately

Is the note true? Only a person who has walked a real case through it may say yes.

Does the workflow run end to end? That is a different question, and a documented organisation is not a working one.

What it looks like an hour in

What needs you, and how it is running

built 2026-09-22 · 13 checks green

Waiting on you

Named, not counted — with what each one waits for and what happens if nothing is done.

Nothing is waiting on you. Everything written down has an owner and a decision.

The organisation

1 department, each with one executive who answers for it. A department with no executive, or no workflow, is named above as waiting on you.

OPERATIONS EXECUTIVE Operations

Somebody who was away for a week can open the picture and know what happened without asking anyone.

- How work actually moves through the organisation — the workflows themselves
- The weekly rhythm: what finished, what is stale, what is next
- The standard for written work: a note somebody else could act on without asking a question

3 workflows, 1 running

Honest on day one

One department, three roles, and it says so. It does not pretend to be an organisation yet.

Green, and it means it

Thirteen checks ran against the notes. The number in the corner is measured, not typed.

Two weeks later, it has found two things

Nobody reported either of them. The page counted them, off the notes, the way it does every time it is built.

What needs you, and how it is running

built 2026-09-22 · 13 checks green

Waiting on you

Named, not counted — with what each one waits for and what happens if nothing is done.

Decision not made: DR — One price list or two

drafted and waiting on you, 14 days ago — until you decide it, everything downstream of it is guessing

Workflow with no owner: Chasing What Is Late

nobody is accountable when it goes wrong, so nobody will notice when it does

Named, never counted. Not “two items need attention” — which decision, how long it has been sitting there, and what it is costing you to leave it.

It tells you when you are wrong

A department invented, and a workflow pointing at one that does not exist — a typo. Three seconds later:

```
FAILED: every department has exactly one executive who answers for it —  
           'Sales' has no executive; every question about it lands back on you  
  
FAILED: every workflow belongs somewhere — 'Running Your Week' belongs to  
           'Delivry', and there is no department note by that name
```

No jargon, no error code, no line number. It names the note and says what it costs you.

Your first hour

- **Make the folder and connect it**
- **Name your departments**
- **Write down the process that annoys you most**
- **Walk one real case through it**

Five minutes, and the only part that touches your computer.

Three to six, out loud, in your own words. Each gets an executive.

One. Including where it breaks.

Only then is it validated — and only you can say so.

Installed in your vault, owned by you. Nothing here phones home.
